Lorenz curve 2 has a less equal distribution than curve 1, given that 40% of income earners only get 5% of the economy's income. Lorenz curves can be used in three fundamental ways: To look at inequality in a single country over a period of time. To compare inequality in two counties. To consider the effect of a policy change on inequality.

Graphical Representation of the Gini Index (Lorenz curve) The Gini coefficient is usually defined mathematically based on the Lorenz curve, which plots the proportion of the total income of the population (y-axis) that is cumulatively earned by the bottom x% of the population. The line at 45 degrees thus represents perfect equality of incomes.

In economics, the Lorenz curve is a graphical representation of the distribution of income or of wealth. It was developed by Max O. Lorenz in 1905 for representing inequality of the wealth distribution. The curve is a graph showing the proportion of overall income or wealth assumed by the bottom x% of the people, although this is not rigorously true for a finite population. It is often used to represent income distribution, where it shows for the bottom x% of households, what percentage of the t

The difference in inequality between each of the 4 wealth components is illustrated in Figure 2.6, which shows the Lorenz curves 1 for the wealth components in the period July 2012 to June 2014. Lorenz curves are a graphical representation of the inequality of distribution; where the diagonal 45 degree line illustrates a scenario where wealth is equally shared.

Lorenz curves. The Lorenz curve is a graph showing how evenly distributed a variable is over space. Example of Lorenz curves. Deprivation in two London Boroughs compared to the English average. The diagonal black line represents a perfectly even distribution. The blue and red lines show uneven distributions.

Let $y = f^{-1}(k+1(x))$ and $y = f^{-1}(k+1(x))$ be the Lorenz curves of $(p, k+1, q, k+1)$ and (p', k', q', k') . Then, for x , we have $f^{-1}(k+1(x)) \geq f^{-1}(k'(x))$. For x , both are satisfied, and hence $(p, k, q, k) \prec (p', k', q', k')$ (i.e., $f^{-1}(k(x)) \geq f^{-1}(k'(x))$ implies $f^{-1}(k+1(x)) \geq f^{-1}(k'+1(x))$).
