## **Optical Integrated Circuits**

An optical integrated circuit (IC) is a compactly packaged electronic circuit, chip, or microchip that processes light directly to perform various communication functions. The advantages in using an optical integrated circuit include the higher maximum data speed that can be sent over an optical link as compared to other means and the freedom from damage due to natural and man-made interference and transient energies.

A photonic integrated circuit or integrated optical circuit is a device that integrates multiple photonic functions and as such is similar to an electronic integrated circuit. The major difference between the two is that a photonic integrated circuit provides functions for information signals imposed on optical wavelengths typically in the visible spectrum or near infrared 850 nm-1650 nm. The most commercially utilized material platform for photonic integrated circuits is indium phosphide, which

Optical integrated circuits  
Researchers hope to put wave guides, modulators, switches, and other active optical functions onto various substrates. It is visualized that thin films and micro-fabrication technologies can suitably be adopted to realize optical counterparts of integrated electronics for signal generation, modulation, switching, multiplexing and processing.
