In this Letter, we point out that the photon helicity in b s can be unambiguously extracted by combining the measurements in B K1 and the Cabibbo-favored D K1e+ decay. We propose a ratio of up-down asymmetries in D K1e+ to quantify the hadronic effects. A method for measuring, in experiment, the involved partial decay widths in the ratio is discussed, and experimental facilities like BESIII, Belle-II and LHCb are likely to measure this ratio.

We discuss the use of helicity methods in evaluating loop diagrams by analyzing a specific example: the one-loop contribution to e+e- qq in massless QCD. By using covariant helicity representations for the spinor and vector wave functions we obtain the helicity amplitudes directly from the Feynman loop diagrams by covariant contraction.

The great simplicity attained by the Weyl-van der Waerden spinor technique in the evaluation of helicity invariant amplitudes is shown to apply in the cumbersome calculations within the framework of linearized gravitation. Once the graviton couplings to spin-0, 1/2, 1, and 3/2 particles are given, we exhibit the reach of this method by evaluating, as an example, the helicity amplitudes for the ...

CP-even Higgs 0 ++ bosons h 0, H 0 couple to the combination 1 - 2 = - 1 2 (1+ 1 2) while a CP-odd 0 - -+ Higgs boson A 0 couples to [1 x 2] - k = 2i 1 (1+ 1 2), where i and i = ± 1 are photon polarization vectors and helicities. The first of these structures couples to linearly polarized photons with the maximal strength if the polarizations are parallel, the latter if the polarizations are perpendicular.

Therefore, in a parity-invariant theory like QED you have to include both the \$+1\$ and \$-1\$ helicity photon fields. The representations do not have to be irreducible, so no one can stop us from thinking about a photon field with two polarizations. Reference [Weinberg] Weinberg, S.
